Introduction

This book describes a number of programs, written in the BASIC\(^1\) programming language. These programs perform a variety of common, practical tasks. The programs are written in a restricted subset of standard BASIC that is compatible with many versions of BASIC now available to microcomputer users.

You can use this book whether or not you know how to write programs in BASIC.

We do not teach you how to program in BASIC; there are probably hundreds of books trying to do that. But we do describe programs carefully and include user examples with the program listings. So if you are not familiar with BASIC, simply copy the program listings into your computer; then run the programs as illustrated in the examples.

Remarks are included in the listings to help BASIC programmers understand how each program works. They will also assist you in identifying parts of programs that you may be able to use in other programs you write. Remark statements precede the line(s) on which they comment. REM statements should be omitted when you enter programs, since they are ignored by the computer and simply use up memory.

Options are also included with some programs. An option is an alteration which changes the input or output format of the original program. Options may suggest ways in which you can further alter the programs. We have included a brief description, example, sample run and partial listing of each option. The partial listing includes those program statements which are changed when going from the original program to the optional program. Lines which must be altered, added or deleted are shaded in both listings.

All programs can be run using a Teletype\(^2\) or similar input/output device with a line width as short as 72 characters. If the line width on your output device is less than 72 characters, you may want to alter the print statements within programs that print longer lines.

Certain programs will require additional programming if you use a CRT display or separate printing device for output. If using a CRT, you will probably want to put a pause in some programs after displaying one screenful of data: otherwise, the data will be displayed faster than you can read it. If using a separate printing device for your output, you may need to add print device select statements to the programs.

All programs in this book have been tested, run and listed on a Wang 2200 computer system. They have also been tested and run on a Commodore PET\(^3\). Some of this testing was with programs modified for better efficiency on the PET.

BASIC Compatibility

Readers of the first and second editions of this book have helped locate typographical and programming errors and have informed us of some compatibility problems for users with different BASICS. For this third edition we have done some reprogramming to eliminate errors and help solve the compatibility problems. Even so, you should be aware of some general compatibility problems which may occur.

1) Some programs may branch out of a FOR/NEXT loop before its iteration is complete. If branching out in the middle of a FOR/NEXT loop causes an error in your BASIC, you can change the FOR/NEXT loop at that point to branch to the NEXT statement, avoiding any program statements which would alter other variable values as the loop completes itself.

2) When a FOR/NEXT loop is completed, the index variable should remain set to its highest value when the program resumes after the loop. For example, in the following program the value of I at line 30 should be 10.

\[
\begin{align*}
10 & \text{ FOR } I = 1 \text{ TO } 10 \\
20 & \text{ NEXT } I \\
30 & \text{ PRINT } I
\end{align*}
\]

---

\(^1\)BASIC is a registered trademark of the Trustees of Dartmouth College.

\(^2\)Teletype is a registered trademark of the Teletype Corporation.

\(^3\)PET is a registered trademark of Commodore, Inc.
Your BASIC may say \( I = 11 \) at line 30. To fix this, add a new line after the NEXT statement to decrement the index variable by one. In the above program, add the following:

\[
25 \ I = I - 1
\]

If you have a BASIC which does not have a FOR/NEXT index variable keep its value outside the loop. you will have to set the variable equal to the end value of the loop once outside the loop (you need to do this only if that index variable value is used later in the program).

3) One variation of the RESTORE command is RESTORE \( n \), where \( n \) refers to the \( n^{th} \) item on the data list. and this \( n^{th} \) item is to be read in the next READ statement. If your BASIC does not accept RESTORE \( n \), change that part of the program to RESTORE, then loop to read data to the \( n^{th} \) item.

4) If your BASIC does not set all variables to zero for each RUN (unless another value is specified in a statement), then you will have to write statements to initialize each variable to zero at the beginning of each program.

5) Some programs use DEF FNR (\( I \)). If not implemented, substitute this expression (with appropriate variable) for each callout of FNR.

6) Some programs use the TAB function with the PRINT statement. You can usually replace it with a string of blanks of the appropriate length. For instance, PRINT TAB(5); A1 could be PRINT "        ; A1.

Program Errors

If you encounter an error or program difficulty which you believe is not your fault, we would like to hear about it. Please write the authors in care of the publishers, and include the following information:

1) description of the error
2) data entered which caused the error
3) source listing of your program, from your computer (if possible)
4) any corrections you have

We appreciate your help in creating a book of tested BASIC programs that anyone can use.
**Future Value of an Investment**

This program calculates a future value of an investment when interest is a factor. You must provide the amount of the initial investment, the nominal interest rate, the number of compounding periods per year and the number of years of investment.

Assuming there are no additional deposits and no withdrawals, the future value is based on the following formula:

\[ T = P(1 + i/N)^N \times Y \]

where:  
- \( T \) = total value after \( Y \) years (future value)  
- \( P \) = initial investment  
- \( i \) = nominal interest rate  
- \( N \) = number of compounding period per year  
- \( Y \) = number of years

**Examples:**

Carl makes an investment of $6800.00 at 9.5%. If interest is compounded quarterly, what will be the value of Carl’s investment in 10 years?

Mr. Smith purchases a piece of property for $16,050.00. The value of property is rising at an average of 7% per year. What may Mr. Smith expect his property to be worth in 5 1/2 years?

:RUN
FUTURE VALUE OF AN INVESTMENT

Future Value of Regular Deposits (Annuity)

This program calculates a future value when deposits are made regularly. All deposits are equal. You must provide the amount of each deposit, the number of deposits per year, the number of years, and the nominal interest rate.

Assuming that interest is compounded with each deposit, the calculation is based on the following formula:

\[ T = R \cdot \left( \frac{(1 + i/N)^{NY} - 1}{i/N} \right) \]

where:
- \( T \) = total value after \( Y \) years (future value)
- \( R \) = amount of regular deposits
- \( N \) = number of deposits per year
- \( Y \) = number of years
- \( i \) = nominal interest rate

Examples:

$50.00 is transferred each month from Matt's checking account to a Christmas Club savings account with 5% interest. How much will Matt receive at the end of the year?

Tim makes annuity payments of $175.00. The interest is 5.5%. What amount will Tim have accumulated in 15 years?

180 . END
Regular Withdrawals from an Investment

This program calculates the maximum amount which may be withdrawn regularly from an investment over a specified time period. All withdrawals are assumed to be equal. You must provide the amount of the initial investment, the nominal interest rate, the number of withdrawals per year and the number of years.

The maximum amount of withdrawals is calculated by the following formula:

\[ R = P \left( \frac{i/N}{(1+i/N)^{N\cdot Y-1}} + \frac{i}{N} \right) \]

where: 
- \( R \) = amount of regular withdrawal 
- \( P \) = initial investment 
- \( i \) = nominal interest rate 
- \( N \) = number of withdrawals per year 
- \( Y \) = number of years

Because this program calculates a maximum amount, a balance of $0.00 will be left in your account at the end of the time period. You may withdraw any lesser amount under the same specifications and leave a remaining balance in your account.

Example:

David invests $8000.00 at 9.5%. He plans to make regular withdrawals every month for ten years, leaving nothing at the end. How much should he withdraw each time?

:RUN
REGULAR WITHDRAWALS FROM AN INVESTMENT

...
Initial Investment

This program calculates the investment necessary to provide a stated future value in a specified time period. You must enter the future value of the investment, the number of years of investment, the number of compounding periods per year and the nominal interest rate.

The formula used to calculate the initial investment is as follows:

\[ P = \frac{T}{(1 + \frac{i}{N})^{N \cdot Y}} \]

where:

- \( P \) = initial investment
- \( T \) = future value
- \( N \) = number of compounding periods per year
- \( Y \) = number of years
- \( i \) = nominal interest rate

Examples:

How much must you invest at 8.5\% to produce $10,000.00 at the end of 10 years if interest is compounded quarterly?

Merchant Savings wishes to sell a bond which will be worth $5000.00 five years from the purchase date. Interest will be 7.9\% compounded daily. How much must the bank charge for the bond?

:RUN
INITIAL INVESTMENT

TOTAL VALUE AFTER \( Y \) YEARS? 10000

90 PRINT "NOMINAL INTEREST RATE";
...  
180 END
```
Minimum Investment for Withdrawals

This program calculates the minimum investment required to allow regular withdrawals over a specified time period. The amount calculated is dependent upon the amount of each withdrawal, the number of withdrawals per year, the number of years, and the nominal interest rate on the investment. All withdrawals are equal.

Only the least amount necessary for your investment is calculated; the program assumes a balance of $0.00 to be left at the end of the time period. Any investment larger than the amount calculated will also enable you to withdraw the desired amount, but leave a remaining balance.

Assuming that interest is compounded with each withdrawal, the calculation is based on the following formula:

\[ P = \frac{R \cdot N}{i} \left( 1 - \frac{1}{(1+i/N)^{N \cdot Y}} \right) \]

where:
- \( P \) = initial investment
- \( R \) = amount of regular withdrawal
- \( i \) = nominal interest rate
- \( N \) = number of withdrawals per year
- \( Y \) = number of years

Example:

How much must you invest at 6% interest to allow monthly withdrawals of $100.00 for 5 years?

::RUN
MINIMUM INVESTMENT FOR WITHDRAWALS

180 END

OPTION

It may be more convenient to enter the term of investment in years and months rather than years. The program changes necessary are listed following the example below.

Example:

Tony withdrew $250.00 monthly for 6 years and 5 months. How much was his initial investment at 6% interest?

:RUN
MINIMUM INVESTMENT FOR WITHDRAWALS

AMOUNT OF WITHDRAWALS? 250
NOMINAL INTEREST RATE? 6
NUMBER OF WITHDRAWALS PER YEAR? 12
NUMBER OF YEARS, MONTHS? 6,5
MINIMUM INVESTMENT = $ 15944.81

MORE DATA (1=YES, 0=NO)? 0

END PROGRAM

PROGRAM LISTING

180 END
Nominal Interest Rate on Investments

This program calculates the nominal interest rate for a known initial investment which amounts to a known future value in a specified period of time. The nominal interest rate is usually subdivided for compounding purposes.

"Nominal Interest Rate" is based on the following formula:

\[
i = \frac{N(T/P)}{N \cdot Y} - N
\]

where:  
\( i \) = nominal interest rate  
\( P \) = initial investment  
\( T \) = future value  
\( N \) = number of compounding periods per year  
\( Y \) = number of years

The nominal interest rate is expressed as a yearly rate even though the interest rate used when compounding interest is \( i \). The nominal interest rate will be less than the effective interest rate when interest is compounded more than once a year. This is because the nominal rate stated does not take into account interest compounded on interest earned in earlier periods of each year. For example, the schedule of earned interest on $100.00 at 5% compounded quarterly would be:

<table>
<thead>
<tr>
<th>PERIOD</th>
<th>BALANCE</th>
<th>( i/100 )</th>
<th>INTEREST</th>
<th>NEW BALANCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>$100.00</td>
<td>.0125</td>
<td>$1.25</td>
<td>$101.25</td>
</tr>
<tr>
<td>2</td>
<td>$101.25</td>
<td>.0125</td>
<td>$1.27</td>
<td>$102.52</td>
</tr>
<tr>
<td>3</td>
<td>$102.52</td>
<td>.0125</td>
<td>$1.28</td>
<td>$103.80</td>
</tr>
<tr>
<td>4</td>
<td>$103.80</td>
<td>.0125</td>
<td>$1.30</td>
<td>$105.10</td>
</tr>
</tbody>
</table>

The effective interest rate in the example is 5.1%, although the nominal rate is 5%.

Examples:

Jane invests $945.00 in a savings bank. Four and a half years later her investment amounts to $1309.79. If interest is compounded monthly, what is the nominal interest rate offered by the bank?

Dick invests $3,000.00. Ten years later he has earned $1,576.00 in interest. If interest is compounded each month, what is the nominal interest rate on the account?

Effective Interest Rate on Investments

This program calculates the effective interest rate for a known initial investment which amounts to a known future value in a specified period of time. This rate expresses the actual rate of interest earned annually on the investment.

The effective interest rate is calculated by the following formula:

\[
\text{effective interest rate} = \left( \frac{\text{future value}}{\text{initial investment}} \right)^{1/\text{years}} - 1
\]

You may calculate the effective interest rate on amounts you have already invested and accrued interest. Or you may calculate the effective interest rate necessary to enable a principal to reach a hypothetical value in a specified amount of time. For instance, if you invest $5000.00 in a bank and desire $6800.00 after six years, you will predict the effective interest rate the bank must pay in order to achieve this.

"Effective Interest Rate" may also be used to calculate the effective percent of depreciation of an investment. Take your car, for example. If you bought it for $7534.00 and sold it for $3555.00 three years later, you will find that its actual depreciation (a negative interest rate) was approximately 22% each year.

Examples:

Jane deposits $945.00 in a savings bank. Four and a half years later her account has $1309.79. What actual percent of her initial investment did the bank pay annually?

Dick bought his car in 1970 for $7534.84 and sold it in 1973 for $3555.00. What was its effective rate of depreciation?

Earned Interest Table

This program calculates and prints an earned interest table for investments. The schedule contains the following outputs:

1) Periodic balance
2) Interest accumulated between two periods
3) Total interest accumulated
4) Effective interest rate

These outputs may be calculated for a single investment or for an initial investment with regular deposits or withdrawals. If the table is to be tabulated for a single investment, you must provide the amount of the initial investment, the nominal interest rate, and the number of compounding periods per year. Your new balance will be printed a maximum of four times per year. If interest is compounded less than four times per year, your new balance will be posted with each interest computation.

If the table is tabulated for regular deposits or withdrawals, you must provide the amount of the initial investment, the nominal interest rate, the number of deposits or withdrawals per year and their amount. In this case it is assumed interest is compounded daily (360-day year). Your new balance will be printed at each deposit or withdrawal.

Examples:

Sally invests $2000.00 at 9.5% in a trust fund for ten years. Interest is compounded monthly. What is her yearly balance and earned interest for the last two years?

John deposits $1000.00 at 8% in a passbook savings account. From each monthly paycheck $50.00 is deposited in this account. What is the earned interest table for the first year of this account?

Ted deposits $1000.00 at 8% in his savings. Each quarter he withdraws $150.00. What is the earned interest table for year one of this account?

Depreciation Amount

This program calculates the dollar amount depreciated within a given year for a depreciating investment. You must provide the original price of the investment, its depreciation rate, and the year of depreciation.

The depreciation amount is calculated by the following formula:

\[ D = P \cdot i \cdot (1 - i)^Y - 1 \]

where:
- \( D \) = depreciation amount
- \( P \) = original price
- \( i \) = depreciation rate
- \( Y \) = year of depreciation

Examples:

Joan bought her car for $4933.76. Her model car depreciates at an average annual rate of 21%. What amount has the car depreciated in each of the first three years she has owned it?

Joan is also concerned about the depreciation of the tape deck in her car. It cost her $155.00 two years ago, and has a depreciation rate of 22%. How much will its value decline in year three?

Principal on a Loan

This program calculates an initial amount borrowed. This amount is dependent upon the interest rate, the amount of regular payments, the number of payments per year and the term of the loan.

The calculation is based on the formula:

\[ P = \frac{R \cdot N}{i} \cdot \left( 1 - \frac{1}{(1+i/N)^{N \cdot Y}} \right) \]

where:  
\( P \) = principal  
\( R \) = regular payment  
\( i \) = annual interest rate  
\( N \) = number of payments per year  
\( Y \) = number of years

Example:

Susan has agreed to pay $250.00 bimonthly for 3 years to repay a loan with 20% interest. What is the amount of the loan?

Tom can afford to make payments of $180.00 per month to repay a loan. If he is willing to make payments for four and a half years and the loan company charges 16% interest, what is the maximum amount Tom can borrow?

Regular Payment on a Loan

This program calculates the amount required as regular payments in order to repay a loan over a specified time period. The specifications you must provide are the amount of the principal, the interest rate charged, the number of payments to be made per year and the number of years to pay. This program assumes all installment payments will be equal.

The calculation is based on the formula:

\[ R = \frac{i \cdot P/N}{1 - \left(\frac{i}{N} + 1\right)^{-N \cdot Y}} \]

where:  
- \( R \) = regular payment  
- \( i \) = annual interest rate  
- \( P \) = principal  
- \( N \) = number of payments per year  
- \( Y \) = number of years

Examples:

What must you pay on a loan of $4000.00 at 8% if payments are to be made quarterly for five years?

If Michael borrows $6500.00 at 12.5% from Best Rate Savings & Loan to be paid back over a period of 5.5 years, what would his monthly payments be?

:RUN

170 END
This program calculates the amount of the final payment on a loan. This final payment will complete amortization of a loan at the conclusion of its term. You must provide the amount of the loan, the amount of the regular payment, the interest rate charged, the number of payments per year and the term of payment.

The amount of the last payment is normally different from the amount of the regular payment. The final payment will be a 'balloon' payment if the final payment is larger than the regular payment. A balloon payment is necessary if applying the amount of the regular payment as the last payment leaves a remaining balance due. In order to entirely pay off the loan at the end of its term, this remaining balance is added to the amount of the regular payment to determine the amount of the last payment.

On the other hand, the amount of the final payment is sometimes less than the regular payment. If the regular payment as the last payment would result in a negative loan balance, then the last payment should be smaller. In this case the regular payment is adjusted by the amount of this hypothetical negative balance to determine the amount of the last payment.

\[
\text{amount of last payment} = \text{regular payment} + \text{hypothetical balance due on a loan after } N \cdot Y \text{ regular payments}
\]

where: \( N \) = number of payments per year
\( Y \) = number of years

Examples:

Lynn borrowed $6000.00 at 5\% from her father for college expenses. If she pays $1000.00 annually for seven years, what will her last payment be?

Lynn borrows $1150.00 at 8\% interest to be repaid at a rate of $75.00 per month. A year and two months later Lynn decides to go to Europe. How much must she pay next month to completely pay off her loan?

Remaining Balance on a Loan

This program calculates the balance remaining on a loan after a specified number of payments. It is necessary for you to provide the amount of the regular payment, the number of payments per year, the amount of the principal, the annual interest rate, and the payment number after which to calculate the remaining balance.

The remaining balance is calculated by the following method:

\[
\text{remaining balance} = \text{principal} - \text{amount amortized after } N \cdot (Y - 1) + N1 \text{ payments}
\]

where:
- \( N \) = number of payments per year
- \( Y \) = year to calculate remaining balance
- \( N1 \) = payment number in year \( Y \) to calculate remaining balance

Example:

Kelly has taken out a loan of $8000.00 at 17.2% interest. His regular payments are $200.00 per month. If he has paid through the tenth payment in the fourth year, how much more does Kelly owe on his loan?

:RUN

250 END
This program calculates the period of time needed to repay a loan. You must specify the amount of the loan, the amount of the payments, the number of payments to be made per year and the annual interest rate on the loan. All payments are assumed to be equal.

The term of payment is derived from the following formula:

\[
Y = \frac{\frac{1}{\log\left(1 + \frac{i}{N}\right)}}{\log\left(1 - \frac{P \cdot i}{N \cdot R}\right)} \cdot \frac{1}{N}
\]

where:
- \( Y \) = term of payment in years
- \( P \) = principal
- \( i \) = annual interest rate
- \( N \) = number of payments per year
- \( R \) = amount of payments

Examples:

What would be the duration of payment on a mortgage of $20,000.00 at 18% when payments of $1000.00 are to be made quarterly?

Sally takes out a loan for $12,669.00 at 16.8%. Her payments are $512.34 every two months. What is the term of her loan?

Annual Interest Rate on a Loan

This program calculates the rate at which interest is charged on a loan. To determine this rate you must enter the amount of the loan, the amount of the regular payment, the number of payments per year, and the term of the loan.

The annual interest rate is computed by the following method of approximation:

1) Guess an interest rate
   Initialize last guess to 0
2) Compute regular payment using guessed rate:
   \[ R_1 = \frac{i \cdot P/N}{1 - (1 + i/N)^{-N \cdot Y}} \]
   Round off \( R_1 \)
3) If computed payment = actual payment, then current guess = approximate interest rate
4) Otherwise, save current guess and calculate a new guess
   \[ i_2 = i \pm \frac{R - R_1}{2} \]
   \[ i = \begin{cases} i_2 & \text{if } R_1 < R \\ i & \text{if } R_1 > R \end{cases} \]
5) Go to 2

where: \( i \) = interest rate
\( i_2 \) = previous interest rate
\( R \) = input regular payment
\( R_1 \) = computed regular payment
\( P \) = principal
\( N \) = number of payments per year
\( Y \) = number of years

Examples:

Cindy borrowed $3000.00 from her friend George with an agreement to pay back $400.00 quarterly for 2 years. At what interest rate is she being charged?

To pay back a loan of $10,000.00 John contracted to make monthly payments of $120.00 for 9.5 years. At what rate is interest being charged?

Mortgage Amortization Table

This program calculates and prints a loan repayment schedule. This schedule provides the following outputs:

1) Payment number
2) Amount of each payment paid as interest
3) Amount of the loan amortized with each payment
4) Balance remaining on the principal at the time of each payment
5) Accumulated interest paid at the time of each payment
6) Amount of the last payment

In addition, the yearly totals of interest paid and amount amortized are tabulated and printed.

To use this program you must supply the amount of the regular payment, the term of payment, the number of payments per year, the amount of the principal and the annual interest rate.

The schedule is calculated in the following manner:

1) Payment number = payment number within each year
2) Amount of each payment paid as interest = remaining balance \cdot i/N
   where: \( i \) = annual interest rate
   \( N \) = number of payments per year
3) Amount amortized with each payment = \( R - I \)
   where: \( R \) = amount of regular payment
   \( I \) = amount of each payment paid as interest
4) Balance remaining = \( P - \Sigma A \)
   where: \( P \) = principal
   \( \Sigma A \) = sum of amounts amortized with each payment to date
5) Accumulated interest = \( \Sigma I \)
   where: \( \Sigma I \) = sum of amounts of each payment paid as interest to date
6) Amount of last payment = \( R + (P - R \cdot N \cdot Y) \)
   where: \( R \) = regular payment
   \( P \) = principal
   \( N \) = number of payments per year
   \( Y \) = number of years

Example:

David needs $2100.00 to pay off some debts. His sister offers him the money at 6% interest. With payments of $75.00 monthly for 2½ years, what is David’s repayment schedule?

This program calculates the greatest common denominator of two integers. It is based on the Euclidean algorithm for finding the GCD:

1) Enter $A, B$
   $A =$ absolute value of $A$
   $B =$ absolute value of $B$
2) Calculate $R = A - B \cdot \lfloor A/B \rfloor$
3) Is $R = 0$? If yes, the GCD = $B$
   If no, go to step 4
4) $A = B$
   $B = R$
5) Go to step 2

Example:
Find the greatest common denominator of 50 and 18, 115 and 150.

:RUN

Area of a Polygon

This program calculates the area of a polygon. You must supply the x- and y-coordinates of all vertices. Coordinates must be entered in order of successive vertices.

The formula used to calculate the area is:

\[ \text{Area} = (x_1 + x_2) \cdot (y_1 - y_2) + (x_2 + x_3) \cdot (y_2 - y_3) + \ldots + (x_n + x_1) \cdot (y_n - y_1) \times \frac{1}{2} \]

where \( n \) = the number of vertices.

The number of vertices you may enter is currently limited to 24. You may increase or decrease this limit by altering statement 30 according to the following scheme:

30 DIM X(n+1), Y(n+1)

Example:

Approximate the area of Lake Boyer.

```
:RUN

   59 REM - TEST FOR END OF PROGRAM
   60 IF A=0 THEN 150
   109 REM - CALCULATE NUMBER OF COMPLETE CIRCLES
   150 END
Coordinate Conversion

This program converts the coordinates of a point given in Cartesian coordinates to polar coordinates, and vice versa.

The formulas for the conversions are:

\[ r = \sqrt{x^2 + y^2} \]
\[ A = \arctangent\left(\frac{y}{x}\right) \]
\[ x = r \cdot \cos(A) \]
\[ y = r \cdot \sin(A) \]

where:

- \( x = \) abscissa \}
- \( y = \) ordinate \} Cartesian coordinates
- \( r = \) magnitude of ray \} polar coordinates
- \( A = \) angle (in degrees) \}

Examples:

Find Cartesian coordinates of the point \((2, 30.5^\circ)\) given in polar coordinates.

If a point is at \((7, 18)\) in the Cartesian system, what are its coordinates in the polar system?

A point is located at \((0, -46.8)\). What is its location in polar coordinates?

Coordinate Plot

This program plots points on a set of coordinate axes. You must provide the x- and y-coordinates of all points to be plotted, the endpoints of the x- and y-axes, and the increment between points on each axis.

The graph is unconventional in that its x-axis runs vertically while its y-axis runs horizontally. In addition, the axes do not necessarily intersect at zero. A reminder as to where the axes intersect is printed at the top of each graph.

The limit on the number of points plotted may be increased or decreased by altering statement 30 in the following manner:

```
30 DIM X(N+1),Y(N+1)
```

where \( N \) = the maximum number of points you wish to plot.

The length of the y-axis is limited by the width of your output device. This program tests for a length not to exceed 70 spaces. The test at statement 90 should be altered to accommodate your particular output device. For an output device with a line width of 112 characters you might enter:

```
90 IF BE<108 THEN 120
```

Example:
The heights of twelve men and their sons are recorded in the table below. Plot the data points.

<table>
<thead>
<tr>
<th>father</th>
<th>65</th>
<th>63</th>
<th>67</th>
<th>64</th>
<th>68</th>
<th>70</th>
<th>66</th>
<th>68</th>
<th>69</th>
<th>71</th>
</tr>
</thead>
<tbody>

Plot of Polar Equation

This program plots a given function in polar coordinates. There are up to 90 points plotted, one every four degrees. (Some points may overlap.)

The graph is conventional in that the x-axis runs horizontally, the y-axis runs vertically, and they intersect at zero. You need only specify the absolute value of the endpoints.

The increment between each point on the x- and y-axes is adjusted so that a value of one on either axis is equidistant from zero. This allows the function to be plotted with minimal distortion. An adjustment of each increment is necessary because of different spacing horizontally and vertically on an output device. (This program assumes ten spaces per inch horizontally and six spaces per inch vertically. If your output device differs, the graph may be distorted.)

It is necessary for you to enter the function to be plotted before you run the program. The function must be entered as a function of $d$. $f(d)$ will be entered and set equal to $F$ at line 130. For example, the function $f(d) = 2(1 - \cos(d))$ will be entered as follows:

130 $F=2*(1-COS(D))$

(Continued on next page)
Example:

Plot the equation \( f(\theta) = 2 \cdot (1 - \cos(\theta)) \).

:130 \( F = 2 \cdot (1 - \cos(D)) \)

Plot of Functions

This program calculates and plots up to nine functions. All functions must be functions of \( x \), and all will be plotted on the same set of axes.

To set up the axes you must input the endpoints of the \( x \)- and \( y \)-axes. You must also state the increment by which the points on each axis are to be increased.

The graph is unconventional in that its \( x \)-axis runs vertically while its \( y \)-axis runs horizontally. To read the graph you must either turn your output 90° counterclockwise or mentally adjust to the change in convention.

The graph is also unconventional in that its axes do not necessarily cross at zero. A reminder as to where the axes cross is printed at the top of each graph.

You must enter the functions to be plotted as program statements prior to running the program. Statement numbers 221 to 229 are reserved for this purpose. Functions must be entered in the number sequence \( Y(1) \), \( Y(2) \),... \( Y(9) \). For example, if you wish to plot the functions \( f(x) = 2x + 1 \) and \( f(x) = \sqrt{x} \), you must type:

\[
\begin{align*}
221 & \quad Y(1) = 2 \times X + 1 \\
222 & \quad Y(2) = \text{SQR}(X)
\end{align*}
\]

The length of the \( y \)-axis is limited by the width of your output device. This program tests for a length not to exceed 70 spaces. The test at statement 140 should be altered to accommodate your particular output device. For example, an output device with a line width of 64 characters would accommodate a graph 62 spaces wide. You would change statement 140 to:

\[
140 \quad \text{IF } Y2 \leq 62 \quad \text{THEN} \quad 170
\]

Linear Interpolation

This program calculates the y-coordinates of points on a line given their x-coordinates. It is necessary to know coordinates of two points on the same line.

The point is interpolated using the following formula:

\[ y = y_1 + \frac{(y_2 - y_1) \cdot (x - x_1)}{(x_2 - x_1)} \]

where:
- \( x_1, y_1 \) = coordinates of first point on the line
- \( x_2, y_2 \) = coordinates of second point on the line
- \( x \) = abscissa of point to be interpolated
- \( y \) = ordinate of the point on the line with \( x \)

Examples:

A conversion table lists 60°F as 15.56°C and 90°F as 32.22°C. Calculate degrees Celsius of 73°F and 85.6°F.

A new sales tax of 17.5% has been imposed on us. What will be the tax on a sofa which sells for $455.68?

Curvilinear Interpolation

This program computes $y$-coordinates of points on a curve given their $x$-coordinates. You must input coordinates of known points on the curve, no two having the same abscissa.

The computations are performed using the Lagrange method of interpolation.

The number of known points on the curve which may be entered in the program is limited to 50. You may increase or decrease this limit by altering statement 30 according to the following scheme:

$$30 \text{ DIM } X(P), \ Y(P)$$

where $P$ = the number of known points on a curve.

Examples:

Consider the curve $y = x^3 - 3x + 3$. You know that the points (-3, -15), (-2, 1), (-1.5), (0, 3), (1, 1), (2, 5), and (3, 21) are on the curve. What is the value of $y$ when $x = -1.65$ and 0.2?

Given the following points from a sine curve, what is the sine of -2.47 and the sine of 1.5?

\[
\begin{array}{ll}
(-5, 958) & (0, 0) \\
(-4, 757) & (1, 841) \\
(-3, -141) & (2, 909) \\
(-2, -909) & (3, 141) \\
(-1, 841) & (4, 757) \\
(5, -959) & \\
\end{array}
\]

Integration: Simpson’s Rule

This program approximates the definite integral of a function. The integral is computed using Simpson’s rule.

The method the program takes is optional: you must supply either the function of the curve or values of the function at specified intervals. For both methods you must enter the limits of integration and the increment between points within the limits.

If the function to be integrated is known, it must be entered before running the program. The function will be defined at line 50. For example, the function \( f(x) = x^3 \) will be entered as follows:

\[
50 \text{DEFFNC}(X)=X^3
\]

Examples:

Find the definite integral of the function \( f(x) = x^3 \) between 0 and 2 with increments of .2 and .1.

What is the integral of a curve between -1 and 1 if the points known are as follows:

\[
(-1,.54) \quad (.25, 969)
\]
\[
(-.75,.73) \quad (.5, 878)
\]
\[
(-.5,.878) \quad (.75, .73)
\]
\[
(-.25, 969) \quad (1,54)
\]
\[
(0,1)

Real Roots of Polynomials:  Newton

This program calculates real roots of a polynomial with real coefficients. You must give an estimate of each root.

The calculations are performed using Newton's method for approximating roots of equations. The value of the error and derivative are included for each root calculated.

The equation you enter is presently limited to a degree of 10. You may enter a larger degree of equation by altering statements 30 and 40 of the program according to the following scheme:

30 REM DIM A(N+1), B(N+1)
40 FOR I=1 TO N+1

where N = degree of equation.

Example:

Find the roots of $4x^4 - 2.5x^2 - x + 0.5$

Roots of Polynomials: Half-interval Search

This program calculates roots of polynomials within a given interval. The program first conducts a random search within the given interval for two points with opposite signs. If a change of sign is found, then the root is calculated by the half-interval search method. If there is no change of sign found, another interval will be asked for.

Errors may result in this program for a couple of reasons. First, a root may be calculated when it should not be. This may happen if the lowest point is so close to zero that a root is found due to round-off error. Second, two roots may be so close together that the program never finds the opposite signs between them. The result in this case is that neither root is calculated.

It is necessary to enter the equation before you run the program. The equation will be defined as a function of $x$ at statement 30. For example, if you want to find roots of the function $f(x) = 4x^4 - 2.5x^2 - x + .5$, you will enter:

```plaintext
30 DEFFNR(X)=4*X^4-2.5*X^2-X+.5
```

Example:

Find a root of the function $f(x) = 4x^4 - 2.5x^2 - x + .5$.

```plaintext
:30 DEFFNR(X)=4*X^4-2.5*X^2-X+.5

Trig Polynomial

This program solves a trigonometric function for a given angle. The function must be in the following form:

\[ f(x) = A_1 \sin(x) + B_1 \cos(x) + A_2 \sin(2x) + B_2 \cos(2x) + \ldots + A_n \sin(n \cdot x) + B_n \cos(n \cdot x) \]

where \( n \) = the number of pairs of coefficients.

The coefficients of the function are to be entered in a data statement at line 30. The data statement will include the number of pairs of coefficients \( n \) and the coefficients of the polynomial. It will be entered as follows:

30 DATA \( n \), \( A_1, B_1, A_2, B_2, \ldots, A_n, B_n \)

Example:

Solve the following equation when the angle equals 45°, 90° and 105°:

\[ f(x) = \sin(x) + 2 \cdot \cos(x) - 2 \cdot \sin(2x) + \cos(2x) + 5 \cdot \sin(3x) - 3 \cdot \cos(3x) \]

Simultaneous Equations

This program solves a system of linear equations. The number of unknown coefficients in each equation must equal the number of equations being solved. You must enter the coefficients of each equation.

The dimension statement at line 30 limits the number of equations which may be solved. You may change this limit according to the following scheme:

\[ :30 \text{ DIM } A(R,R+1) \]

where \( R \) = the maximum number of equations.

Example:

Solve the following system of equations:

\[
\begin{align*}
    x + 2x + 3x &= 4 \\
    3x + 6x &= 1 \\
    -3x + 4x - 2x &= 0
\end{align*}
\]

\[ :30 \text{ DIM } A(3,4) \]
\[ :\text{RUN} \]

Linear Programming

This program uses the simplex method to solve a linear programming problem. You must provide the coefficients of the objective function and the coefficients, relation and constant of each constraint. This information is entered in DATA statements before you run the program.

After you load the program, enter the DATA statements according to the following instructions. If you run more than one problem, remember to clear out all DATA statements from the previous problem before running the new problem. Our DATA statements begin at line 3000.

1) Arrange your problem constraints according to their relation, so that the "less than" inequalities precede the equalities, which in turn precede the "greater than" inequalities.

2) Type in as DATA the coefficients of the constraints, in the order the constraints were arranged in step 1. Do not include coefficients for slack, surplus, or artificial variables. Do include a '0' coefficient for any variable that doesn't appear in a particular constraint.

3) Type in as DATA the constants of the constraints (right-hand sides of the constraints) in the same order as you entered the rows of coefficients. These values cannot be negative.

4) Type in as DATA the coefficients of the objective function.

You must select whether the problem solution is to be a minimum or maximum value. The program also asks you to enter the total number of constraints and the number of variables to allow for each, and the number of "less than", "equal" and "greater than" constraints you are considering.

The dimension statement at line 20 limits the number of variables and constraints you may enter. You can change these limits according to the following scheme:

```
20 DIM A(C+2, V+C+G +1), B(C+2)
```

where:  
C = number of constraints  
V = number of variables  
G = number of "greater than" constraints

Example:

A manufacturer wishes to produce 100 pounds of an alloy which is 83% lead, 14% iron, and 3% antimony. He has available five alloys with the following compositions and prices:

<table>
<thead>
<tr>
<th>alloy 1</th>
<th>alloy 2</th>
<th>alloy 3</th>
<th>alloy 4</th>
<th>alloy 5</th>
</tr>
</thead>
<tbody>
<tr>
<td>90</td>
<td>80</td>
<td>95</td>
<td>70</td>
<td>30</td>
</tr>
<tr>
<td>5</td>
<td>5</td>
<td>2</td>
<td>30</td>
<td>70</td>
</tr>
<tr>
<td>5</td>
<td>15</td>
<td>3</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>$6.13</td>
<td>$7.12</td>
<td>$5.85</td>
<td>$4.57</td>
<td>$3.96</td>
</tr>
</tbody>
</table>

How should he combine these alloys to get the desired product at minimum cost?

Note that this problem results in the following system of equations:

\[
\begin{align*}
 x_1 + x_2 + x_3 + x_4 + x_5 &= 100 \\
 .90x_1 + .80x_2 + .95x_3 + .70x_4 + .30x_5 &= 83 \\
 .05x_1 + .05x_2 + .02x_3 + .30x_4 + .70x_5 &= 14 \\
 .05x_1 + .15x_2 + .03x_3 + .03x_4 + x_5 &= 3 \\
 6.13x_1 + 7.12x_2 + 5.85x_3 + 4.57x_4 + 3.96x_5 &= Z \text{ (min)}
\end{align*}
\]

Matrix Addition, Subtraction, Scalar Multiplication

This program adds or subtracts two matrices, or multiplies a matrix by a given scalar. You must input the value of each element of each matrix. To perform addition or subtraction the dimensions of the two matrices must be equal.

The dimension of the matrices may be increased or decreased depending on the amount of memory available in your system. Statement 30 may be changed to:

```
30 DIM A(X,Y), B(X,Y)
```

where \((X,Y)\) is your limit on the dimension of the matrices.

Example:

Find the sum of the following matrices, then multiply the resultant matrix by 3.

\[
\begin{bmatrix}
1 & 0 & -1 \\
5 & 8 & .5 \\
-1 & 2 & 0
\end{bmatrix}
\quad \begin{bmatrix}
-5 & -1 & 2 \\
6 & -.1 & 0 \\
3 & 4 & -2
\end{bmatrix}
\]

Matrix Multiplication

This program multiplies two matrices. The first matrix is multiplied by the second. You must input the elements of each matrix.

In order for this operation to be performed the number of rows in the first matrix must equal the number of columns in the second matrix.

The dimensions of the matrices are presently limited to 10 x 10. This limit may be increased or decreased by altering line 30 according to the following scheme:

30 DIM A(X,Y), B(Z,X)

where:  (X,Y)  =  dimension of matrix 1
         (Z,X)  =  dimension of matrix 2

Example:
Multiply matrix 1 by matrix 2.

Matrix Inversion

This program inverts a square matrix. The inversion is performed by a modified Gauss-Jordan elimination method.

The dimensions of the matrix are presently limited to 10 x 10. This limit may be increased or decreased by altering line 30 according to the following scheme:

30 DIM A(R,R), B(R,R)

where $R =$ number of rows (or columns) in the matrix.

Example:

Invert matrix A.

\[
A = \begin{pmatrix}
3 & 5 & -1 & -4 \\
1 & 4 & -7 & -3 \\
0 & -2 & 0 & 1 \\
-2 & 6 & 0 & 0.3
\end{pmatrix}
\]

Mann-Whitney U Test

This program performs the Mann-Whitney U test on samples from two populations.

The dimension statement on line 30 limits the size of the samples. You can increase or decrease the dimension limits according to the following scheme:

\[ \text{DIM } X(M), Y(N) \]

where: \( M \) = maximum size of first sample
\( N \) = maximum size of second sample

Example:
A group of ten women and a group of ten men were asked to rate the flavor of a frozen T.V. dinner on a scale of one to ten. The table below lists the scores. Count the number of times the women’s scores are lower than the men’s, and vice-versa.

Using the Poisson distribution this program calculates the probability of an event occurring a given number of times. You must know the expected frequency of the event.

Example:

2000 people are injected with a serum. The probability of any one person having a bad reaction is .001. Thus we can expect two (.001*2000=2) individuals will suffer a bad reaction. What is the probability that four people will have bad reactions? Only one person?

Normal Distribution

This program calculates the probability and frequency of given values on a standard normal distribution curve. You can use non-standard variables if you know the mean and standard deviation.

The shaded area represents the probability of \( x \). \( y \) corresponds to the frequency of \( x \).

The normal probability is approximated using the following formula:

\[
\text{probability} = 1 - r(a_1 t + a_2 t^2 + a_3 t^3) + \epsilon(x)
\]

where:

\[
\begin{align*}
    a_1 &= .4361836 \\
    a_2 &= -.1201676 \\
    a_3 &= .9372980 \\
    r &= (e^{-x^2/2})(2\pi)^{-1/2} \\
    t &= (1 + .3326x)^{-1} \\
    |\epsilon(x)| &< 10^{-5}
\end{align*}
\]

Example:

The mean weight of the male students at a college is 150 pounds. The standard deviation is 15 pounds. If the weights are normally distributed, what is the probability that a student weighs between 150 and 180 pounds? Between 130 and 150 pounds?

Chi-square Distribution

This program calculates the tail-end value for points on a chi-square ($X^2$) distribution curve. You must provide the value of $X^2$ and the degrees of freedom.

The shaded area represents the tail-end value of $X^2$.

The $X^2$ distribution function is calculated using the following formulas:

- with $v$ odd, tail-end value $= 1 - \frac{(X^2)(v + 1)/2 \cdot e^{X^2/2}}{1 \cdot 3 \cdot 5 \cdots v} \cdot \left(\frac{2}{X^2 \pi}\right)^{\frac{1}{2}} \cdot Z$
- with $v$ even, tail-end value $= 1 - \frac{(X^2)v/2 \cdot e^{X^2/2}}{2 \cdot 4 \cdots v} \cdot Z$

where $v = \text{degrees of freedom}$

$$Z = 1 + \sum_{m=1}^{\infty} \frac{(X^2)^m}{(v + 2) \cdot (v + 4) \cdots (v + 2m)}$$

Since the summation in the calculation of $Z$ cannot actually extend to infinity, we stop summation when the next term is less than a chosen level of precision. The computational precision is limited to approximately $10^{-7}$.

**Example:**

Of a group of 168 people who complained they did not sleep well, 54 were given sleeping pills and the remainder received placebos. They were later asked whether or not the pills had helped them sleep. The $X^2$ statistic for this study was computed to be 2.571108 with one degree of freedom. What is the tail-end value?

Student's $t$-distribution

This program calculates right-tail values for points on a $t$-distribution curve. You must provide the value of $t$ and the degrees of freedom.

The shaded area represents the right-tail value for $t$.

The right-tail value is approximated using the following formula:

$$\text{right-tail value} = \frac{1}{4}(1 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4)^{-4} + \epsilon(x)$$

where:

- $a_1 = 0.196854$
- $a_2 = 0.115194$
- $a_3 = 0.000344$
- $a_4 = 0.019527$

$$x = \left( t^{\frac{2}{d}} (1 - \frac{2}{d}) - \frac{7}{9} \right) \left( \frac{2}{9} + t^{\frac{2}{d}} \cdot \frac{2}{9}d \right)^{-\frac{1}{2}}$$

$$d = \text{degrees of freedom}$$

$$|\epsilon(x)| < 2.5 \cdot 10^{-4}$$

Examples:

What is the right-tail value when the $t$-value is 2.921 and there are 16 degrees of freedom?

What is the right-tail value when the $t$-value is 11.178 and there are 5 degrees of freedom?

Student's $t$-distribution Test

This program calculates the $t$-statistic and degrees of freedom for Student's distribution. The calculations can be based on any one of three hypotheses.

The first hypothesis assumes that one population mean is equal to a given value. You must enter the elements of the sample and the value of the mean.

The remaining hypotheses compare two populations. In both tests the means of the two populations are equal, but the standard deviations may be equal or unequal. For these hypotheses you must enter the elements of each sample.

The dimension statement at line 30 limits the size of the samples you may enter. You can change the limit according to the following scheme:

```
30 DIM P(N,2)
```

where $N$ = maximum sample size.

Examples:

A sample of children's IQ's was taken, the results being 101, 99, 120, 79, 111, 98, 106, 112, 87, and 97. Calculate the $t$-statistic assuming the population mean is 100.

A second sample was taken, the results being 101, 95, 130, 150, 75, 79, 111, 100, 98 and 91. Calculate the $t$-statistic based on the hypothesis that the two samples have equal means and standard deviations.

**F -distribution**

This program calculates percentile values for given values on an F -distribution curve. You must provide the value of \( F \), the degrees of freedom in the numerator and the degrees of freedom in the denominator.

![The F -distribution](image)

The area of the shaded region represents the percentile.

The \( F \) -distribution function is approximated using the following formula:

\[
\text{percentile} = 1 - \frac{1}{2} \left( 1 + a_1 y + a_2 y^2 + a_3 y^3 + a_4 y^4 \right)^4 + \epsilon(y)
\]

where:

\[
\begin{align*}
  a_1 &= .196854 \\
  a_2 &= .115194 \\
  a_3 &= .000344 \\
  a_4 &= .019527
\end{align*}
\]

\[
\begin{align*}
  y &= (F^{1/3} (1 - \frac{2}{9d_2}) - (1 - \frac{2}{9d_1}) (\frac{2}{9d_1} + F^{1/3} \cdot \frac{2}{9d_2})^{-1/2}) \\
  d_1 &= \text{degrees of freedom in numerator} \\
  d_2 &= \text{degrees of freedom in denominator} \\
  |\epsilon(y)| &< 2.5 \times 10^{-4}
\end{align*}
\]

**Examples:**

What is the percentile on an \( F \) -distribution curve when the \( F \)-value is .474 and the degrees of freedom are 1 and 18?

You may prefer to compute the tail-end value (the area of the unshaded region in the figure above). The program changes necessary are listed following the examples below.

Examples:

What is the tail-end value on an F-distribution curve when the F-value is .474 and the degrees of freedom are 1 and 18?

What is the tail-end value when the F-value is 23.7 and the degrees of freedom are 3 and 6?
RUN
F-DISTRIBUTION

(TO END PROGRAM ENTER AN F-VALUE OF 0)
F-VALUE? .474
DEGREES OF FREEDOM IN NUMERATOR? 1
DEGREES OF FREEDOM IN DENOMINATOR? 18
TAIL END VALUE = .5063

F-VALUE? 23.7
DEGREES OF FREEDOM IN NUMERATOR? 3
DEGREES OF FREEDOM IN DENOMINATOR? 6
TAIL END VALUE = 1.6000000E-03

F-VALUE? 0

END PROGRAM

X=1-X
PRINT "TAIL END VALUE =";X
PRINT
GOTO 40

END
Linear Correlation Coefficient

This program computes the coefficient of correlation between two variables. A linear relationship is assumed between the variables. You must enter the coordinates of a group of data points forming the regression line.

Example:

The height of twelve men and their sons is recorded in the table below. What is the coefficient of correlation between the heights of fathers and the heights of their sons?

<table>
<thead>
<tr>
<th>father</th>
<th>65</th>
<th>63</th>
<th>67</th>
<th>64</th>
<th>68</th>
<th>62</th>
<th>70</th>
<th>66</th>

Multiple Linear Regression

This program finds the coefficients of a multiple variable linear equation using the method of least squares. The equation is of the following form:

\[ y = c + a_1 x_1 + a_2 x_2 + \ldots + a_n x_n \]

where:  
\( y \) = dependent variable  
\( c \) = constant  
\( a_1, a_2 \ldots a_n \) = coefficients of independent variables \( x_1, x_2, \ldots x_n \)

The constant and the coefficients are printed.

You must provide the \( x \) - and \( y \) -coordinates of known data points. Once the equation has been found using the data you enter, you may predict values of the dependent variables for given values of the independent variables.

The dimension statement at line 30 limits the number of known data points the equation may contain. You can change this limit according to the following scheme:

\[ 30 \text{ DIM } X(N+1), S(N+1), T(N+1), A(N+1,N+2) \]

where \( N \) = the number of known data points.

Example:

The table below shows the age, height and weight of eight boys. Using weight as the dependent variable, fit a curve to the data. Estimate the weight of a seven year old boy who is 51 inches tall.

Geometric Regression

This program fits a geometric curve to a set of coordinates using the method of least squares. The equation, coefficient of determination, coefficient of correlation and standard error of estimate are printed.

You must provide the $x$ - and $y$ -coordinates of known data points. Once the curve has been fitted you may predict values of $y$ for given values of $x$.

Example:

The table below gives the pressures of a gas measured at various volumes in an experiment. The relationship between pressure and volume of a gas is expressed by the following formula:

$$PV^K = C$$

where: $P$ = pressure  
$V$ = volume  
$C$ and $K$ are constants.

This formula can be rewritten in standard geometric form:

$$P = CV^{-K}$$

Note the exponent is negative, which accounts for the negative exponents the program calculates.

Fit a geometric curve to the data and estimate the pressure of 90 cubic inches of the gas.

System Reliability

This program calculates the reliability of an operating system that is subject to wearout and chance failure. You must enter the system's operating time and the wearout time and failure rate of each component.

Example:
Compute the reliability of a computer system operating for 1000 hours with the components shown in the list below.

<table>
<thead>
<tr>
<th>Component</th>
<th>Wearout (hrs.)</th>
<th>Failure Rate</th>
</tr>
</thead>
<tbody>

Average Growth Rate, Future Projections

This program calculates the average growth rate of a company, then projects figures for future years. The growth rate and projections could be computed for any aspect of a company, such as sales, earnings, number of employees, or patronage. You must provide established figures for a past series of years.

The dimension statement at line 30 limits the number of past figures you may enter. Any need to alter this limit should be done in the following manner:

```
30 DIM S(N)
```

where \( N \) = the number of years for which figures are known.

Example:

The borrowing records for Claremount County Library are tabulated in the graph below. What is its average growth rate? How many books can it expect to lend in its tenth and twentieth years of service?

![Graph showing borrowing records for Claremount County Library](image)

```plaintext
:30 DIM S(9)
:RUN

Federal Withholding Taxes

This program calculates the amount of federal income and FICA taxes withheld from one's earnings. You must provide employee information as to marital status, the number of exemptions claimed, the amount of taxable pay, and year-to-date taxable pay.

The number of pay periods per year is established at line 80. If your pay period is other than monthly, you must alter this statement to set \( N \) equal to the number of pay periods per year.

There is a considerable amount of tax information which may change from year to year. The values listed in the data tables at lines 30 and 40 are among those that may need periodic revision. The annual values for single and married persons should be compared each year with those listed in Table 7 of the current IRS Circular E.

The annual FICA rate, the FICA cutoff amount and the annual amount of withholding allowance may also need revision. The values established at lines 50, 60 and 70 should also be compared to those listed in the current IRS circular.

Annual rates and cutoffs are used irrespective of your actual pay period frequency. The program automatically adjusts them to match your pay period.

Examples:

Judy earns $900.00 per month. The payroll clerk is figuring her March paycheck. Judy is single and claims only herself as a dependent. What amounts are withheld from her paycheck?

Dr. Berger has earned $1,408.75 this month. So far this year he has grossed $20,188.72. He is married and claims four dependents. What amounts will be withheld this month for the federal government?

Tax Depreciation Schedule

This program tabulates annual depreciation amounts. You can use the sum of digits method or any declining balance percentage method. You must know the purchase price (initial value), salvage value at the end of the depreciable life, and the life of the item being depreciated. If you are doing declining balance depreciation, you must also know the percentage method.

Examples:

The Miracle Corporation put a new roof on their office building for $27,000.00. They expect to replace it in nine years. What would the annual depreciation amounts be using the sum of digits?

Heavenly Bank built a new home office building for $1.2 million. Run a tax depreciation schedule on the building using 150% declining balance method with a 30 year life. Assume a salvage value of $250,000. You will notice that the depreciation falls below straight line ($31,666.67 per year) at year nine.

Check Writer

This program prints a check. You must provide the date, amount and payee of the check. The program translates the date and amount to words and prints providing spacing within the check.

You should regard the program listed below as a sample of a check-writing program. Very few checks will conform exactly to the spacing provided in this program. The method of translating words from numbers is generally applicable. Spacing should be altered to conform to your own check format.

When the program asks the question READY TO PRINT CHECK? it is prompting you to insert a blank check in your printing device. The check should be set one line above the line on which the date is to be printed.

Once the check is set up, key RETURN (no other entry is required) and the check will be printed.

Example:

Among the checks that Miracle Corporation must write are one to Osborne & Associates for $4975.89 and one to Freida Alexander for $103.75. Print the checks using the computer.

Recipe Cost

This program calculates the cost and the cost per serving of a single recipe. For each ingredient you must provide the purchase price, the amount purchased, the amount used in the recipe, and the number of recipe units per purchase unit.

Example:

Listed below is a recipe for strawberry shortcake. Calculate the cost of the recipe and the cost per serving. What would the cost per serving be if one cake serves 12? The conversion factors and price per ingredient are supplied.

Strawberry Shortcake — 8 servings

OPTION

As you become familiar with the operation of this program you may wish to shorten it by entering the information required for each ingredient on one line. The program changes necessary are listed following the example below.

Example:

Calculate the cost per serving of Strawberry Shortcake in the previous example when it is served without cream.

Survey Check (Map Check)

This program calculates the error of closure and area of a plot for which a traverse of the perimeter is available. The program will also calculate how far North and East the end of an open traverse is from its origin (the Northing and Easting). The local coordinates of the origin can be entered for an open traverse. Negative values of Northing and Easting are South and West, respectively, of the 0,0 origin of the survey.

The individual legs of the traverse may be either straight lines or arcs of circles. To compute the traverse, you must have the bearing and length of each straight leg. You also need the radius, bearing of chord, and length of chord (or radius, arc measure, and bearing of a tangent) for each curved leg.

For a closed survey, pick any intersection of legs as a starting point, and number the lines and arcs, starting with one, in a clockwise direction around the perimeter. If any arc is 180 degrees or more, it must be broken into smaller arcs, each less than 180 degrees.

By convention, surveyors measure bearings East and West of North and South, as shown in the following figure. This convention was established in the days before computers, so that trigonometric functions could be easily looked up in tables not exceeding 90 degrees. For each leg, you must enter the quadrant number and the degrees, minutes and seconds East or West of the North-South axis. The program will indicate the direction of the leg (e.g., SW), and will convert the quadrant, degrees, etc. to an azimuth angle. Azimuth is measured clockwise from North to 360 degrees.

A curved leg, or arc, is defined by two auxiliary legs, each of which is a radius of the arc. The bearing of the first auxiliary leg is the direction of the radius from the first encountered end of the arc to the center of the arc. You can compute this bearing from the bearing of the arc’s tangent at that point, since the radius is perpendicular to the tangent. The survey may show the bearing of the tangent. If not, you can compute it by adding one half the angular extent of the arc to the bearing of the arc’s chord, as shown in the next figure.

Bearing of Tangent = Bearing of Chord + $\frac{\delta}{2}$
The bearing of the second radius is from the center of the arc to the other end, and the distance is entered as a negative number to signal to the computer that this and the prior leg are not perimeter legs, but auxiliary legs of an arc.

The program asks you for the bearing and distance of each leg by number. Legs are entered in sets of ten (or less). Following the last entry in a set, you can correct any leg in the set. You must enter both auxiliary legs of an arc in the same set. You can enter a bearing of zero to end one set, and then enter more legs on the next set.

When you have corrected a set, a traverse table is printed for the set. This includes each leg number, direction, azimuth angle and distance, and incremental and cumulative Northing and Easting. The cumulative Northing and Easting after the last leg on a closed survey gives the error of closure. Arc angle, radius, sector area, chord length, and tangent length are printed between the two auxiliary legs of each curved leg.

Following the printout of the last leg of a closed survey, the area of the plot will be printed, both in square feet and in acres. The area computed is very accurate provided two conditions are met:

1) the error of closure is small (0.01 feet is usual for a house lot), and
2) the area is sufficiently small that curvature of the earth does not become significant. Surveys covering several tens of miles have to account for this latter factor.

Example:

The figure below illustrates the boundaries of a lot with one curved side. The leg numbers are circled. Bearings and distances are shown for each leg. Find the error of closure and lot area.

This program calculates the day of the week that a given date falls on. It will figure, for example, that December 25, 1980 will be a Thursday.

You must enter the date in numeric form and in the order of month, day, year. September 12, 1975 will be entered as 9, 12, 1975, making certain that commas, not slashes or dashes, separate the figures.

Examples:
Cindy's birthdate is March 4, 1953. On what day was she born?

Uncle Lon has an appointment on September 30, 1977. What day is that on?

Days between Two Dates

This program calculates the number of days between two given dates. Leap years are taken into account. The program assumes there is one day between today and tomorrow. For instance, there are two days between March 1 and March 3 of the same year.

There are a few precautions to assure the proper use of this program. First, you must be certain to enter the earlier date first. Second, dates must be entered in number form (3, not MARCH) and in the correct order (month, day, year, i.e., 3,17,1976). Commas, not slashes or dashes, must separate the figures. Third, the year must not be abbreviated (1976, not 76), even if both dates are in the same century. Finally, the month entered must not be greater than 12 and the days no greater than the number of days in the particular month. If such is the case, the message UNREAL DATE is printed to alert you to the fact that an unreal date (such as 14,32,1975) has been entered. An incorrect answer is likely to result.

Example:
John's birthdate is August 8, 1951. How many days old will he be on his 30th birthday?

:RUN
DAYS BETWEEN TWO DATES

FIRST DATE? 8,8,1951
SECOND DATE? 8,8,1981
DIFFERENCE = 10958 DAYS

MORE DATA (1=YES, 0=NO)? 0

END PROGRAM

This program converts a measure given in anglo units to metric units. The conversions available in this program are as follows:

1. Inches to centimeters
2. Feet to centimeters
3. Feet to meters
4. Yards to meters
5. Miles to kilometers
6. Teaspoons to cubic centimeters
7. Tablespoons to cubic centimeters
8. Cups to liters
9. Pints to liters
10. Quarts to liters
11. Gallons to liters
12. Bushels to liters
13. Pecks to liters
14. Ounces to grams
15. Pounds to kilograms
16. Tons to kilograms
17. Degrees Fahrenheit to degrees Celsius

You must provide the value of the anglo measurement and the number of the conversion (1 - 17 as listed above) which you wish to perform.

Example:

Perform the following conversions:

8.5 miles to kilometers
75° Fahrenheit to degrees Celsius
10 gallons to liters

:RUN
ANGLO TO METRIC

(TO END PROGRAM ENTER 0)

WHICH CONVERSION DO YOU NEED? 5
VALUE TO BE CONVERTED? 8.5
8.5 MILES = 13.6765 KILOMETERS

WHICH CONVERSION DO YOU NEED? 17
VALUE TO BE CONVERTED? 75
75 DEGREES FAHRENHEIT = 23.8888888889 CELSIUS

WHICH CONVERSION DO YOU NEED? 11

Alphabetize

This program alphabetizes a list of words or phrases.

Numbers may be part of an alphanumeric phrase. However, they will not be put into numeric order unless they contain the same number of digits. Numbers with fewer digits must be justified to the right by prefixing zeros. Thus, if the numbers you are sorting range into the hundreds, the number 13 would be entered as 013.

To save memory space, the array at statement 70 should be limited to the maximum number of terms you wish alphabetized. The dimension statement should be altered in the following manner:

\[70 \text{ DIM A}(N)\]

where \(N\) = the number of items to be alphabetized.

Example:

Alphabetize the following names:

Robert Wilson
Susan W. James
Kent Smith
Michael Mitchell
Ann T. McGowan
Alexander Lee II
Mary Mitchell
David Bowers
Steven Evans
Carol Jameson
Linda North

:70 DIM A$(11)

Conversions of OSBORNE/McGraw-Hill's Some Common BASIC Programs are being made so the 76 programs are ready to run on many popular systems. A conversion is available from OSBORNE on cassette for the Commodore PET, and conversions will soon be released on cassette and disk for a variety of systems. Independent consultants and businesses are also marketing their own conversions. For further information about these magnetic surfaces, fill out the form below and mail it to OSBORNE/McGraw-Hill (a photocopy of the form will do).

Cut out and mail this request form to:

Some Common BASIC Programs Conversions
OSBORNE/McGraw-Hill
630 Bancroft Way
Berkeley, California 94710

Name: __________________________________________
Street: __________________________________________
City: ___________________________________________
State: ___________ Zip: ___________

Please send further information regarding conversions of Some Common BASIC Programs for the following:
□ Commodore PET
□ TRS-80 Level II
□ Other microcomputer

System: __________________________________________
SOME COMMON BASIC PROGRAMS is designed for people who can use a variety of practical BASIC programs. The programs are written in a restricted version of standard BASIC and are compatible with many versions of BASIC now available to microcomputer users. Program descriptions, examples, and remarks accompany the listings to help you follow BASIC programming logic.

All 76 programs from this book are also available on cassettes or disks for several popular small computer systems including the Commodore PET®8, Radio Shack TRS-80, and Apple II. Contact the publishers for more information.

OSBORNE/McGraw-Hill has published a series of books which provide complete source listings for BASIC business programs, complete with detailed user documentation.

The programs published are:

Payroll with Cost Accounting, Accounts Payable and Accounts Receivable, and General Ledger

Each book includes complete source listings, file layouts, file maintenance programs, interactive operator data entry sequences, screen display formats, and report printout formats. Every program is accompanied by user instructions, program flowcharts, and narrative descriptions. All programs feature interactive data entry with easy correction of data entry errors. Contact the publishers for more information.
